#### Abstract

Electrical properties of molecules are difficult to compute accurately, and traditional calculations typically require large basis sets with multiple sets of diffuse and polarization functions. Ditchfield, Sadlej, and Almlöf have shown that much smaller basis sets can be used if electric dependence is incorporated into the basis set. We have combined the features of these methods and allowed the center of each Gaussian, $\mathbf{A}$, to depend on the field, $\epsilon$, according to $\mathbf{A}(\epsilon)=\mathbf{A}(0)-\alpha^{n} \lambda \epsilon$, where $\alpha$ is the Gaussian exponent, $n$ is a fixed integer, and $\lambda$ is a parameter chosen to maximize the polarizability in a series of reference molecules. The field dependence is used in both the exponential and the preexponential factors in the Gaussian basis functions. Electric field dependent $\mathrm{HF} / 6-31+\mathrm{G}^{* *}$ calculations of dipole moments, polarizabilities, and infrared intensities are approximately the same quality as HF/6-311++G(3d,3p) calculations without field dependent functions (the improvement is most striking for the polarizabilities of linear molecules). Field dependence of the outer valence and diffuse functions appears to be the most important. The results for $n=-2$ and $n=0$ are very similar; the existing codes for geometrical derivatives of the energy can be easily modified to compute improved electrical properties for the $n=0$ case.

## Introduction

The dipole moment vector, $\mu$, the polarizability tensor, $\alpha$, and the infrared intensities, $A$, are important molecular properties. They provide information about the distribution of charge within a molecule and how it changes with an applied electrical field and with molecular vibrations. Unfortunately, electrical properties are notoriously difficult to calculate accurately because they depend on the outer parts of the wave function. ${ }^{1}$ One approach is to use a very large basis set, augmented with multiple diffusion and polarization functions, to provide more flexibility in the valence region of the wave function (see refs $2-4$ for examples). However, such calculations can be quite expensive except for small molecules.
An alternate approach is to use a modest size basis set and to build in some functional dependence on the applied electric field. Three different approaches have been tried previously. Ditchfield ${ }^{5}$ used field dependent basis functions of the form

$$
\begin{align*}
& \phi=\left(x-A_{x}\right)^{1 \mathrm{Ax}}\left(y-A_{y}\right)^{1 \mathrm{~A} y}\left(z-A_{z}\right)^{1 \mathrm{~A} z} \times \\
& \exp \left(-\alpha(\mathbf{r}-\mathbf{A})^{2}\right) \exp (k \epsilon \cdot(\mathbf{r}-\mathbf{A})) \tag{1}
\end{align*}
$$

where $k$ is chosen to maximize the molecular polarizability (different $k$ for each shell in the basis). Sadlej ${ }^{6}$ used basis functions of the form

$$
\begin{align*}
& \phi=\left(x-A_{x}\right)^{1 \mathrm{Ax}}\left(y-A_{y}\right)^{1 \mathrm{~A} y}\left(z-A_{z}\right)^{1 \mathrm{~A} z} \times \\
& \quad \exp \left(-\alpha\left(\mathbf{r}-\mathbf{A}+\lambda \epsilon / \alpha^{2}\right)^{2}\right) \tag{2}
\end{align*}
$$

where $\lambda$ is chosen to maximize the molecular polarizability and $\lambda$ is different for $x, y, z$ directions but the same $\lambda$ 's are used for all Gaussians in the molecule. Both approaches improved the dipole moments and polarizabilities significantly for calculations with small basis sets. Almlöf and co-workers ${ }^{7}$ incorporated an electric field dependence into the wave function by variationally optimizing the positions of each contracted basis function in the molecule in the presence and absence of the field. Properties calculated with a smaller basis set (double- $\zeta$ with one set of diffuse and polarization functions) were found to be close to the Hartree-

[^0]Fock limit. However, some functions occasionally floated an unreasonable distance away from the nuclear centers. ${ }^{7}$

We have tested an approach that combines features of Ditchfield's, Sadlej's, and Almlöf's methods. The center for each Gaussian is chosen to depend on the electric field according to

$$
\begin{equation*}
\mathbf{A}(\boldsymbol{\epsilon})=\mathbf{A}-\alpha^{n} \lambda \boldsymbol{\epsilon} \tag{3}
\end{equation*}
$$

where $\lambda$ is isotropic to maintain rotational invariance but different $\lambda$ 's are used for each shell for flexibility. The field dependent $\mathbf{A}(\boldsymbol{\epsilon})$ is used in the preexponential factors as well as in the exponential part of the Gaussian basis functions

$$
\begin{align*}
& \phi=\left(x-A_{x}(\epsilon)\right)^{1 \mathrm{Ax}}\left(y-A_{y}(\epsilon)\right)^{1 \mathrm{~A} y}\left(z-A_{z}(\epsilon)\right)^{1 \mathrm{~A} z} \times \\
& \exp \left(-\alpha(\mathbf{r}-\mathbf{A}(\epsilon))^{2}\right) \tag{4}
\end{align*}
$$

The field dependent parameters $\lambda$ are chosen to maximize the atomic polarizabilities computed with the same basis set.

## Computational Methodology

The molecular energy, $E$, can be expanded in terms of the applied electric field, $\epsilon$ :

$$
\begin{align*}
& E(\epsilon)=E(0)+\sum_{\alpha}\left(\frac{\partial E(\epsilon)}{\partial \epsilon_{\alpha}}\right)_{\epsilon_{\alpha=0}} \epsilon_{\alpha}+ \\
& \frac{1}{2} \sum_{\alpha} \sum_{\beta}\left(\frac{\partial^{2} E(\epsilon)}{\partial \epsilon_{\alpha} \phi \epsilon_{\beta}}\right)_{\epsilon_{\alpha} \epsilon_{\beta}=0} \epsilon_{\alpha} \epsilon_{\beta}+\ldots \tag{5}
\end{align*}
$$

where $E(0)$ is the energy of the molecule in the absence of the field, and $\epsilon_{\alpha}$ and $\epsilon_{\beta}$ are the Cartesian components of the electric field. The components of the permanent dipole moments and polarizability tensor are

$$
\begin{equation*}
\mu_{\alpha}=-\left(\frac{\partial E(\epsilon)}{\partial \epsilon_{\alpha}}\right)_{\epsilon_{\alpha=0}} \tag{6}
\end{equation*}
$$

${ }^{a}$ Polarizabilities in au, ${ }^{3}$ experimental values quoted in refs 5 and 6 . Order of $\lambda$ 's: core, inner and outer valence, diffuse and polarization.

$$
\begin{equation*}
\alpha_{\alpha \beta}=-\left(\frac{\partial^{2} E(\epsilon)}{\partial \epsilon_{\alpha} \partial \epsilon_{\beta}}\right)_{\epsilon_{\alpha} \epsilon_{\beta}=0} \tag{7}
\end{equation*}
$$

In the double harmonic approximation, the infrared intensity of the $i$ th vibrational mode, $A_{i}$, is proportional to the square of the change in the dipole moment with the vibration

$$
\begin{equation*}
A_{i}=\frac{N \pi d_{i}}{3 c^{2}}\left|\frac{\partial \mu}{\phi Q_{i}}\right|^{2} \tag{8}
\end{equation*}
$$

where $N$ is Avogadro's number, $d_{i}$ is the degeneracy of the $i$ th mode, $c$ is the speed of light, and $\partial \mu / \partial Q_{i}$ is the derivative of the dipole moment with respect to the normal mode coordinate $Q_{i}$.

If the basis functions do not depend on the applied electric field, the dipole moment in the Hartree-Fock, approximation can be calculated as the expectation value of the dipole moment operator.

$$
\begin{equation*}
\mu^{0}=\left\langle\sum_{i} q_{i} \mathbf{r}_{4} \mathrm{i}\right\rangle=-\sum_{\mu \nu} P_{\mu \nu}\langle\mu| \mathbf{r}|\nu\rangle+\sum_{\mathrm{A}}^{\mathrm{L}} Z_{\mathrm{A}} R_{\mathrm{A}} \tag{9}
\end{equation*}
$$

where $P_{\mu \nu}$ is the Hartree-Fock density matrix in the absence of an applied field, $Z_{\mathrm{A}}$ are the nuclear charges, and $R_{\mathrm{A}}$ are the nuclear positions. The polarizability is the derivative of the dipole with respect to the field

$$
\begin{equation*}
\alpha^{0}=-\left(\frac{\partial^{2} E}{\partial \epsilon^{2}}\right)=\left(\frac{\partial \mu}{\partial \epsilon}\right)=-\sum_{\mu \nu} P_{\mu \nu}^{\epsilon}\langle\mu| \mathbf{r}|\nu\rangle \tag{10}
\end{equation*}
$$

where $P_{\mu \nu}^{\epsilon}$ is the derivative of the density matrix with respect to the applied field and is obtained by solving the coupled perturbed Hartree-Fock equations (CPHF). ${ }^{8}$ The dipole derivative is the

${ }^{a}$ Polarizabilities in au. ${ }^{3}$
derivative of the dipole with respect to the positions of the nuclei

$$
\begin{equation*}
\left(\frac{\partial \mu}{\partial R}\right)^{0}=-\sum_{\mu \nu}\left[P_{\mu \nu}^{R}\langle\mu| \mathbf{r}|\nu\rangle+P_{\mu \nu}\langle\mu| \mathbf{r}|\nu\rangle^{R}\right]+\sum_{\mathrm{A}}^{\mathrm{L}} Z_{\mathrm{A}} \tag{11}
\end{equation*}
$$

where $\langle\mu| \mathbf{r}|\nu\rangle^{R}$ are the derivatives of the dipole moment integral with respect to the atom positions.

If the basis functions depend on the applied field, the one- and two-electron integrals also depend on the field. Since the electrical properties are defined as derivatives with respect to the applied field, there are additional terms arising from the derivatives of these integrals that contribute to the dipole moment, polarizability, and dipole derivatives:

$$
\begin{gather*}
\mu=-\left(\frac{\partial E}{\partial \epsilon}\right)=\mu^{0}-\sum_{\mu \nu}\left[P_{\mu \nu}\left(h_{\mu \nu}^{\epsilon}+\frac{1}{2} \sum_{\lambda \sigma} P_{\lambda \sigma}\langle\mu \nu \| \lambda \sigma\rangle^{\epsilon}\right)-\right. \\
\alpha=-\left(\frac{\partial^{2} E}{\partial \epsilon^{2}}\right)=\alpha^{0}-\sum_{\mu \nu}\left[P _ { \mu \nu } \left(h_{\mu \nu}^{\epsilon \epsilon}+\right.\right.  \tag{12}\\
\left.\left.\frac{1}{2} \sum_{\lambda \sigma} P_{\lambda \sigma}\langle\mu \nu \| \lambda \sigma\rangle^{\epsilon \epsilon}\right)+P_{\mu \nu}^{\epsilon} F_{\mu \nu}^{\epsilon \epsilon}-W_{\mu} S_{\mu \nu}^{\epsilon \epsilon}-W_{\mu \nu}^{\epsilon} S_{\mu \nu}^{\epsilon}\right] \\
\left(\frac{\partial \mu}{\partial R}\right)=\left(\frac{\partial \mu}{\partial R}\right)^{0}-\sum_{\mu \nu}\left[P_{\mu \nu}\left(h_{\mu \nu}^{\epsilon R}+\frac{1}{2} \sum_{\gamma \sigma} P_{\lambda \sigma}\langle\mu \nu \| \lambda \sigma\rangle^{\epsilon R}\right)+\right.  \tag{13}\\
\left.P_{\mu \nu}^{R} F_{\mu \nu}^{(\epsilon)}-W_{\mu \nu} S_{\mu \nu}^{\epsilon R}-W_{\mu \nu}^{R} S_{\mu \nu}^{\epsilon}\right]
\end{gather*}
$$

In the above equations, the superscript 0 indicates the property computed without field dependent functions, $W_{\mu \nu}$ is the Lagrangian, and $\epsilon$ and $R$ are derivatives with respect to the field and the nuclei. The Fock matrix derivative, $F_{\mu \nu}^{(\epsilon)}$, is defined as

$$
\begin{equation*}
F_{\mu \nu}^{(\epsilon)}=h_{\mu \nu}^{\epsilon}+\sum_{\lambda \sigma} P_{\mu \nu}\langle\mu \nu \| \lambda \sigma\rangle^{\epsilon} \tag{15}
\end{equation*}
$$

The derivatives of the density $P_{\mu \nu}^{\epsilon}$ and $P_{\mu \nu}^{R}$, the Lagrangian $W_{\mu \nu}^{*}$ and $W_{\mu \nu}^{R}$, and the Fock matrix $F_{\mu \nu}^{(\epsilon)}$ are obtained by solving the CPHF equations. ${ }^{8}$ The Gaussian 92 suite of programs ${ }^{9}$ has been modified to calculate the necessary integral derivatives with
the scalar Rys-quadrature routines and to assemble the field dependent basis function contributions to the electrical properties.

## Results and Discussion

Table 1 lists the optimal values of $\lambda$ for $\mathrm{H}, \mathrm{F}, \mathrm{C}$, and O for the $4-31 \mathrm{G}, 6-31 \mathrm{G}^{* *}$, and $6-31+\mathrm{G}^{* *}$ basis sets. These were obtained by maximizing the polarizability for $\mathrm{H}_{2}, \mathrm{HF}, \mathrm{CH}_{4}, \mathrm{H}_{2} \mathrm{O}$, respectively, using the experimental geometries (the $\lambda$ 's for H in $\mathrm{HF}, \mathrm{CH}_{4}$, and $\mathrm{H}_{2} \mathrm{O}$ were fixed at the optimal values obtained for $\mathrm{H}_{2}$ ). Comparison with nonfield dependent calculations (i.e. $\lambda=$ 0 ) shows that field dependent functions yield significant improvement in the polarizabilities for all three basis sets. The field dependent HF/6-31+G** results appear to be superior to the conventional calculations with the much larger $6-311++G(3 \mathrm{~d},-$ 3 p ) basis set. Most of the improvement is obtained when electric field dependent functions are used for the outer valence and diffuse functions. Very little is gained when the polarization functions are field dependent. The results for $n=0$ and $n=-2$ are almost identical. The $n=0$ case is particularly attractive, since the integrals needed are the same as above those used for geometric derivatives, and these can be computed efficiently with any welloptimized energy derivative package.
To gain confidence that the outer and diffusion functions contribute the most to the improvement of the polarizability, calculations were carried out with $\lambda$ 's set at different fractions of the optimal value of $\lambda$. Table 2 shows that when $\lambda$ is changed from its optimal value to zero for either the core, inner valence, or polarization functions, the polarizability changes by less than $1 \%$ for all cases. For the outer valence and diffusion functions, the effect is more significant. For the hydrogen molecule computed with the $4-31 \mathrm{G}$ basis set, setting $\lambda=0.0$ for the outer valence function reduces the polarizability by $50 \%$; qualitatively similar results are found for $\mathrm{HF}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{NH}_{3}$. With the $6-31+G^{* *}$ basis set, field dependence is more important for the diffuse functions than for the outer valence functions. Setting $\lambda=0$ for the diffuse function reduces the polarizability by $10-$ $25 \%$ for $\mathrm{H}_{2}, \mathrm{HF}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{NH}_{3}$. Both of these effects are much smaller for nonpolar molecules such as methane. The polarizability does not seem to be too sensitive to the exact value of $\lambda$. A $25 \%$ change in $\lambda$ for all of the calculations produces errors no greater than $2.3 \%$, and a $10 \%$ change produces errors no larger than $1 \%$. However, the optimal values for $\lambda$ are quite different for each basis set on a given atom and are not transferable between basis sets.
Calculated dipole moments, polarizabilities, and IR intensities for $\mathrm{H}_{2}, \mathrm{HF}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{CH}_{2}, \mathrm{CH}_{4}, \mathrm{CO}, \mathrm{CO}_{2}, \mathrm{HCN}, \mathrm{C}_{2} \mathrm{H}_{2}, \mathrm{H}_{2^{-}}$

a Dipole mopments in au; polarizabilities in au; ${ }^{3}$ infrared intensities in $\mathrm{km} / \mathrm{mol}$ listed in order of increasing frequency (symmetry forbidden modes not included); experimental data quoted in refs $2-7$.
$\mathrm{CO}, \mathrm{C}_{2} \mathrm{H}_{4}, \mathrm{CH}_{3} \mathrm{~F}$, and $\mathrm{CH}_{2} \mathrm{~F}_{2}$ are listed in Table 3. The geometries are optimized at the basis sets at which the calculations are performed, and the optimal $\lambda$ values for the atoms were taken from Table 1. For all of the molecules in Table 3, the dipole moments computed with the field dependent $6-31+\mathrm{G}^{* *}$ basis are within 0.04 D of the value obtained with the $6-31++G(3 \mathrm{~d}, 3 \mathrm{p})$ basis without field dependent functions. Even the field dependent $4-31 \mathrm{G}$ calculations are within 0.1 D of the $6-31++\mathrm{G}(3 \mathrm{~d}, 3 \mathrm{p})$ values.

For the hydrogen molecule, the perpendicular components of the polarizability, $\alpha_{x x}$ and $\alpha_{y y}$, are zero with 4-31G basis set without electric field dependence. With the nonfield dependent
$6-31++\mathrm{G}^{* *}$ basis, the polarization functions contribute to the perpendicular components, yielding $\alpha_{x x}=\alpha_{y y}=0.564$ au versus 5.424 au with electric field dependent functions. With the $6-31++G^{* *}$ basis, the parallel component is well represented without field dependent functions at 6.558 au. With field dependent corrections, the value of 6.322 au for $\alpha_{z z}$ is in better agreement with the basis set $6-311++\mathrm{G}(3 \mathrm{~d}, 3 \mathrm{p})$ and the experimental value.

Similar trends are found for other linear molecules (HF, CO, $\mathrm{CO}_{2}, \mathrm{HCN}$, and $\mathrm{C}_{2} \mathrm{H}_{2}$ ). Field dependent functions change the parallel component very little ( $0.2-1.4$ au at $4-31 \mathrm{G}$ ) but change the perpendicular components much more (3-8 au at $4-31 \mathrm{G}$ ).

Increasing the basis set size without field dependence has a large effect on the perpendicular components because of the polarization functions but has only a modest effect on the parallel component. With field dependence functions, increasing the basis set size has relatively little effect on either components. Adding diffuse functions increases the polarizability both with and without polarization functions.

For nonlinear molecules, it is difficult to partition the polarizability into parallel and perpendicular contributions for each bond. However, the behavior of the isotropic polarizability is similar to the linear molecules. Polarizabilities computed with field dependent functions are much less sensitive to basis set size than computations without field dependent functions. Field dependent calculations at the $\mathrm{HF} / 6-31+\mathrm{G}^{* *}$ level in most cases are as good as or better than HF/6-311++G(3d,3p) computations without field dependence. Furthermore, there is very little difference ( $\pm 0.03 \mathrm{au}$ or less) between $n=-2$ and $n=0$ in the field dependent calculations.

The improvement in the IR intensities is much less spectacular than for the polarizabilities. Intensities calculated at the 4-31G level, both with and without field dependence, can be significantly in error when compared to the HF/6-311++G(3d,3p) values. In general, using field dependent functions tends to reduce the IR intensity (however, there are a few exceptions). At the HF/6$31+G^{* *}$ level, calculations with field dependent functions almost always yield intensities that are closer to the HF/6-311++G( $3 \mathrm{~d}, 3 \mathrm{p}$ ) values than HF/6-31+G** calculations without field dependence. As with the polarizabilities, $n=0$ and $n=-2$ give nearly the same results (average differences of less than $1 \mathrm{~km} /$ mol ). Comparison of IR intensities is not as simple because accurate experimental values of absolute intensities are difficult to obtain. Schaefer ${ }^{2}$ and Houk ${ }^{3}$ have shown that much of the remaining differences between the Hartree-Fock and the experimental IR intensities are due to electron correlation and that calculations of IR intensities at second-order Moller-Plesset perturbation theory with a small basis set (e.g. MP2/6-31+G*) are able to predict the correct qualitative information about the ordering of the intensities.

## Conclusion

As discussed in previous papers, the use of electric field dependent functions can improve the calculated values of
electrical properties. The improvements in the polarizabilities are more impressive than the dipole moments and IR intensities, and the largest improvements in the polarizabilities are in the components perpendicular to the bond. Field-dependent $\mathrm{HF} / 6-31+\mathrm{G}^{* *}$ calculations are approximately the same quality as $\mathrm{HF} / 6-311++\mathrm{G}(3 \mathrm{~d}, 3 \mathrm{p})$ calculations without field-dependent functions. The results for $n=-2$ and $n=0$ are very similar; the latter has the advantage that existing integral derivative routines can be used to compute the extra terms arising from the fielddependent basis functions.
